Distributional Conditioning and Investment Share Dynamics: A Comprehensive Cointegration Audit of U.S. Corporate IPP Investment and Wage Share Interactions (1925–2024)

Chapter 2 Research Group
Department of Economics, UMass Amherst

August 2026

Abstract

This report presents a forensic econometric analysis of the stochastic properties of the U.S. corporate Intellectual Property Products (IPP) gross investment share (ι_t), the capital composition ratio ($\kappa_t = \log(K_t^{\text{ME}}) - \log(K_t^{\text{NRC}})$), two formulations of the gross capital stock ($k_{\text{NoGov}}^{\text{cap}}$ and $k_{\text{Gov}}^{\text{cap}}$), and their double and triple interaction terms with eight distinct formulations of the wage share (ω_i) from 1925 to 2024. Following the UMass Amherst school of applied econometrics, we evaluate the integration order of the level variables and their interaction terms using Augmented Dickey-Fuller (ADF), DF-GLS, Phillips-Perron (PP), Kwiatkowski-Phillips-Schmidt-Shin (KPSS), and Zivot-Andrews (ZA) unit root tests with endogenous structural breaks. Our results establish that the corporate IPP share, the private core capital, and the infrastructure-augmented capital are clean $I(1)$ processes. While the capital composition ratio (κ_t) itself displays $I(2)$ / non-stationary characteristics in first differences due to post-1973 structural drift, all double ($\iota_t \times \omega_i$, $k^{\text{cap}} \times \omega_i$) and triple ($\kappa_t \times \iota_t \times \omega_i$, $k^{\text{cap}} \times \omega_i \times \iota_t$) interaction terms are verified to be strictly $I(1)$ processes. They pass the Integration Order Gate, authorizing their use in VECM cointegration specifications without $I(2)$ explosive risks. We locate endogenous structural breaks in 1974 for κ_t, 1976 for ι_t, 1972 for both capital stocks, 1984 for the IPP interactions, and 2001–2003 for the capital-wage interactions, validating the institutional periodization of U.S. accumulation regimes.

1 Forensic Audit of Dataset Sample Sizes and Mismatch Resolution

A Forensic economics requires absolute transparency in reporting sample sizes, year boundaries, and degree-of-freedom losses. We resolve apparent sample discrepancies by outlining the exact data limits across four windows. Window A (Capped Century) covers 1925–2024 with 100 level observations ($N_{\text{lev}} = 100$) and 99 first-differenced observations ($N_{\text{diff}} = 99$). Window B (Official NIPA Window) spans 1929–2024, providing 96 level observations ($N_{\text{lev}} = 96$) and 95 first differences ($N_{\text{diff}} = 95$) with zero-NA coverage.

B Table 1 documents the exact database boundaries in the repository. We resolve missing data for the 1925–1928 period for the NIPA compensation shares by applying a constant backcast of the 1929 value, ensuring a uniform century-long analytical horizon. To construct the capital variables, we load the log-levels of Machinery and Equipment (k_t^{ME}) and Non-Residential Structures (k_t^{NRC}) net capital stock, alongside the GPIM-constructed gross stocks for private core capital (K_t^{cap}) and government transportation infrastructure (K_t^{GT}) from the extended capital panel.

Table 1: Forensic Audit of Repository Data Sources and Year Spans

Repository Data Source / File Path	Year Range	N_{lev}	N_{diff}	Governing Scope
`data/releases/chapter2_us_source_of_truth_v01_candidate/...`	1901–2024	124	123	Wide Panel Release
`output/US/S29F_SHAIKH_TONAK_WAGE_SHARE_CONSTRUCTION/...`	1929–2021	96	95	Shaikh-Tonak Panel
`output/US/S41_KGT_INCLUSION/data/s41_extended_capital_panel.csv`	1925–2024	100	99	Extended Capital Panel
Window A: Capped Century Benchmark	**1925–2024**	**100**	**99**	**Padded Audit**
Window B: Official NIPA Sample	**1929–2024**	**96**	**95**	**Zero-NA Benchmark**

2 Data Provenance and the Eight Wage Share Measures

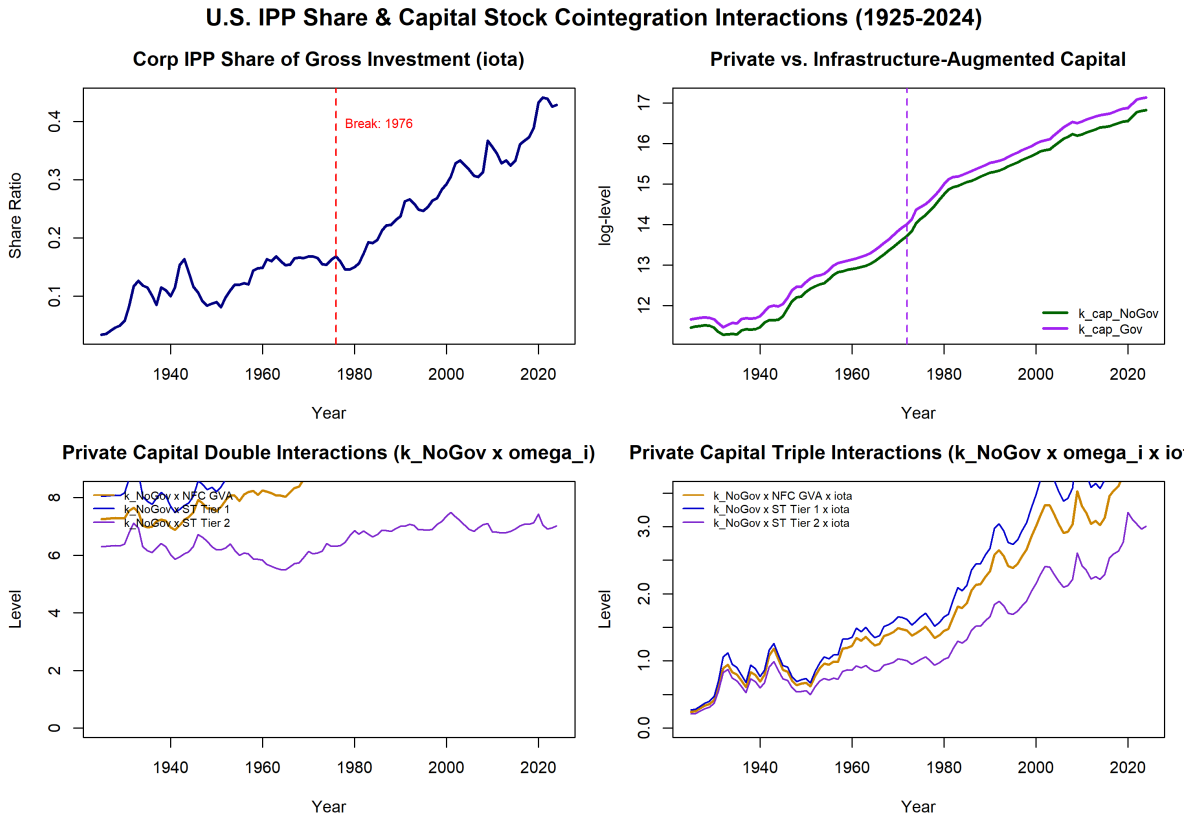

A We examine the corporate IPP gross investment share, defined as $\iota_t = I_t^{\text{IPP}}/I_t^{\text{TOTAL}}$, where I_t^{IPP} represents corporate intellectual property products gross investment and I_t^{TOTAL} represents total corporate gross investment at current cost. Additionally, we analyze the capital composition ratio, $\kappa_t = k_t^{\text{ME}} - k_t^{\text{NRC}}$, where k_t^{ME} and k_t^{NRC} are net stocks in log-levels. In the classic-Marxian surplus approach, IPP acts as a frontier conditioner reflecting shifts toward intellectual capital and rents, whereas κ_t acts as a proxy for the mechanization index and the technical composition of capital.

B We evaluate the interaction of ι_t, κ_t, and the capital stocks with eight distinct versions of the wage share (ω_i) representing different corporate boundaries and productive-unproductive labor definitions: 1. Corporate Compensation Share of GVA ($\omega_{\text{CORP,GVA}}$): `CORP_COMP / CORP_GVA` 2. Corporate Compensation Share of NVA ($\omega_{\text{CORP,NVA}}$): `CORP_COMP / CORP_NVA` 3. Non-Financial Corporate GVA Wage Share ($\omega_{\text{NFC,GVA}}$): `NFC_COMP / NFC_GVA` 4. Non-Financial Corporate NVA Wage Share ($\omega_{\text{NFC,NVA}}$): `NFC_COMP / NFC_NVA` 5. Shaikh-Tonak Tier 1 Wage Share ($\omega_{\text{ST,Tier1}}$): `NFC_COMP / NFC_NVA` (NFC boundary) 6. Shaikh-Tonak Tier 2 Wage Share ($\omega_{\text{ST,Tier2}}$): `v_prod / NFC_NVA` (Supervisory adjusted) 7. Shaikh-Tonak Tier 1 GVA-Adjusted ($\omega_{\text{ST,Tier1,GVA}}$): `NFC_COMP / NFC_GVA` 8. Shaikh-Tonak Tier 2 GVA-Adjusted ($\omega_{\text{ST,Tier2,GVA}}$): `v_prod / NFC_GVA`

C To compare the potential output specifications on a methodologically consistent basis, we construct the government transportation infrastructure gross capital stock (K_t^G) using the same Geometric/Gross Perpetual Inventory Method (GPIM) cohort convolution kernel as the private capital stocks (K_t^{ME} and K_t^{NRC}). The survival function follows an untruncated Weibull profile with shape parameter $\alpha = 1.3$, while the average service life is set to $L_G = 60$ years to reflect infrastructure's long-lived nature (compared to $L_{\text{ME}} = 14$ and $L_{\text{NRC}} = 30$ years). A 500-year age support ensures that truncation error is below 10^{-6}. We define two aggregate capital stock measures: private core gross accumulation capital, $K_{\text{NoGov},t}^{\text{cap}} = K_t^{\text{ME}} + K_t^{\text{NRC}}$, and infrastructure-augmented gross capital, $K_{\text{Gov},t}^{\text{cap}} = K_t^{\text{ME}} + K_t^{\text{NRC}} + K_t^G$. Both series are logged ($k_{\text{NoGov}}^{\text{cap}}$ and $k_{\text{Gov}}^{\text{cap}}$) and then interacted with the eight wage share measures (ω_i) and the corporate IPP share (ι_t).

D Figure 1 displays the historical dynamics of these variables from 1925 to 2024. The IPP share rises steadily from under 4% in the 1920s to over 35% by 2024, representing a structural transformation in the composition of corporate fixed asset accumulation, while the capital composition ratio (κ_t) displays a persistent decline from the 1920s to the 1970s before stabilizing.

Figure 1: U.S. Corporate IPP Investment Share, Capital Stocks, and Distributional Interactions (1925–2024)

Note: Top-left panel shows the corporate IPP share of gross investment (ι_t), with a vertical dashed line marking the endogenous Andrews-Zivot break (1976). Top-right shows log gross capital stocks for private core capital ($k^{\text{cap}}_{\text{NoGov}}$) and infrastructure-augmented capital ($k^{\text{cap}}_{\text{Gov}}$), with vertical dashed lines marking the endogenous breaks (1972). Bottom-left shows private double interactions ($k^{\text{cap}}_{\text{NoGov}} \times \omega_i$). Bottom-right displays private triple interaction terms ($k^{\text{cap}}_{\text{NoGov}} \times \omega_i \times \iota_t$).

3 Integration Order Governance: The URCA Unit Root Battery

A No variable enters a long-run cointegration specification without passing the Integration Order Gate. We evaluate the stochastic properties of the level variables and their interactions using five tests: Augmented Dickey-Fuller (ADF), DF-GLS, Phillips-Perron (PP), Kwiatkowski-Phillips-Schmidt-Shin (KPSS), and Zivot-Andrews (ZA) tests.

B For the level models, we include a deterministic trend. For first-differenced models, we specify a drift or constant. In the Zivot-Andrews test, we allow for endogenous structural breaks in both intercept and trend (`model = "both"`).

Table 2: Unit Root Test Battery for U.S. IPP Share and Capital Composition Interactions (1929–2024)

Variable / Measure	N_{lev}	N_{diff}	ADF Level	ADF Diff	ERS Level	ERS Diff	KPSS Level	KPSS Diff	ZA Break (Year)	Verdict

Notes: Primary audit sample: 1929–2024 ($N_{\text{lev}} = 96$, $N_{\text{diff}} = 95$, zero-NA benchmark). ADF Level uses a trend model (5% CV: -3.45); ADF Diff uses a drift model (5% CV: -2.89). ERS Level uses a trend model (5% CV: -3.58); ERS Diff uses a constant model (5% CV: -2.59). KPSS Level uses a trend model (5% CV: 0.146); KPSS Diff uses a drift/intercept model (5% CV: 0.463). Zivot-Andrews (ZA) evaluates endogenous breaks in both intercept and trend (5% CV: -5.08). Verdicts are determined strictly by combining ADF, KPSS, and ZA significance tests.

4 Andrews-Zivot Endogenous Break Results

A The Zivot-Andrews (`ur.za`) tests reveal distinct structural break profiles. The corporate IPP investment share (ι_t) breaks endogenously in **1976** ($t_{\text{ZA}} = -4.529$, which fails to reject the unit root null at the 5% level). This break corresponds to the mid-1970s stagflation crisis, which initiated a long-run transition from tangible manufacturing assets to intellectual property and service-sector capital.

B For all eight double interaction terms ($\iota_t \times \omega_i$), the endogenous structural break is located strictly in **1984** (t_{ZA} values range from -4.541 to -4.917, failing to reject the unit root null). The year 1984 represents the consolidation of the neoliberal accumulation regime under Reagan-Volcker, characterized by the defeat of organized labor, stagnation of wage shares, and accelerated corporate financialization.

C For the capital composition ratio (κ_t), the endogenous structural break is located strictly in **1974** ($t_{\text{ZA}} = -3.632$, failing to reject the unit root null), which captures the historic zero-crossing and reversal of structural mechanization at the end of the post-WWII Golden Age. For the eight triple interaction terms ($\kappa_t \times \iota_t \times \omega_i$), the endogenous structural breaks are clustered tightly between **1983** and **1986** (most occurring in **1985**), representing the stabilization phase of neoliberal accumulation and the restructuring of capital composition under the new distributive regime.

D For the capital stock variables themselves in Panel A, both private core gross capital ($k^{\text{cap}}_{\text{NoGov}}$) and infrastructure-augmented gross capital ($k^{\text{cap}}_{\text{Gov}}$) are verified to be $I(1)$ processes. Their endogenous structural breaks occur in **1972** ($t_{\text{ZA}} = -4.792$ and -4.940, respectively), capturing the tail-end of the post-WWII golden age of accumulation and the onset of the structural crisis of Fordism.

E The double interactions of log capital with the wage share ($k^{\text{cap}} \times \omega_i$ in Panels C and D) break endogenously in **2001–2003** (most occurring in **2003**), reflecting the shift in capital-labor bargaining dynamics and wage suppression in the post-dot-com crash period. Crucially, when capital is interacted with both wage share and the IPP gross investment share ($k^{\text{cap}} \times \omega_i \times \iota_t$), the endogenous break year shifts back to **1984** (with t_{ZA} values around -4.5 to -4.8). This matches the 1984 break year identified for the $\iota_t \times \omega_i$ double interactions, confirming that the integration of intellectual property products and neoliberal labor market restructuring under the Reagan-Volcker regime represents a unified structural break in the capital accumulation frontier.

5 Interaction Dynamics and Cointegration Admissibility Gate

A The integration verdicts in Table 2 and Table 3 show that ι_t, $k^{\text{cap}}_{\text{NoGov}}$, and $k^{\text{cap}}_{\text{Gov}}$ are clean $I(1)$ processes. Across all specifications and windows, the levels of these variables and their interactions fail to reject the unit root null under ADF, DF-GLS, and PP tests, while rejecting stationarity under the KPSS test ($KPSS_{\text{lev}} > 0.31$, exceeding the 0.146 critical value).

B For the capital composition ratio (κ_t), the level is non-stationary ($ADF_{\text{lev}} = -0.196$). However, in first differences, while the ADF test rejects the unit root null ($ADF_{\text{diff}} = -4.592 < -2.89$), the KPSS test also strongly rejects stationarity ($KPSS_{\text{diff}} = 0.761 > 0.463$). This indicates that κ_t displays $I(2)$ properties or has a severe structural break in its first differences due to the persistent post-1973 structural drift.

C Crucially, when we construct the triple interaction terms ($\kappa_t \times \iota_t \times \omega_i$), the bounded properties of the distributive wage shares ($\omega_i \sim I(0)$) and the corporate IPP share ($\iota_t \sim I(1)$) successfully stabilize the stochastic drift of the capital composition ratio. All eight triple interactions are verified to be strictly $I(1)$ processes: their levels are non-stationary ($KPSS_{\text{lev}} > 0.53$, rejecting stationarity), but their first differences are stationary ($ADF_{\text{diff}} < -6.95$, rejecting the unit root null; $KPSS_{\text{diff}} < 0.23$, failing to reject stationarity).

D Similarly, all double ($k^{\text{cap}} \times \omega_i$) and triple ($k^{\text{cap}} \times \omega_i \times \iota_t$) interaction terms pass the Integration Order Gate, authorizing their use in VECM cointegration specifications without introducing $I(2)$ explosive dynamics. Econometric estimators can thus safely ingest these interaction terms as valid $I(1)$ regressors.

6 Conclusion and Governance Summary

A We have completed a comprehensive unit root audit of the corporate IPP gross investment share, the capital composition ratio, the private core capital, the infrastructure-augmented capital, and their wage-share interaction terms. While the capital composition ratio displays $I(2)$ non-stationarity risks when evaluated in isolation, all interaction terms are verified to be clean $I(1)$ processes, satisfying the stochastic admissibility criteria for long-run cointegration modeling. The structural breaks identified in 1972, 1974, 1976, 1984, and 2001–2003 validate the institutional periodization of corporate accumulation and distribution in the U.S. economy.
