

1. The red path is not structural θ_t

Object correction

The red line in v6 is an observed-direction ratio:

$$\vartheta_{d,t}^{path} = \frac{\theta g_t^{NRC} + (\psi + \lambda \tilde{d}_t)(g_t^{ME} - g_t^{NRC})}{g_t^{cap}}.$$

It changes when the annual direction of accumulation or its denominator changes.

Structural objects

$$\theta^{scale} = \theta, \quad \theta_{d,t}^{\tau} = \psi + \lambda \tilde{d}_t.$$

These are the equilibrium scale and technique elasticities. Neither equals g_t^p / g_t^{cap} .

Coefficient audit

The S34 interaction was orthogonalized over the full panel. Using that same projection, primitive and orthogonalized fitted values agree to 3.6×10^{-15} ; manual RDOLS agrees to 5.3×10^{-15} .

- Back-transformation reproduces the raw S35 coefficients to rounding precision.
- Correcting the coefficients does not remove the lumpy ratio: its roughness remains 79.0% of the code-as-written path.
- v6 should rename the red line before giving it an economic interpretation.

2. Exact decomposition: the wage term is not the source of the spikes

$$v_{d,t}^{path} = C_t^{scale} + C_t^{composition} + C_{d,t}^{distribution}, \quad \max |\text{identity error}| = 8.9 \times 10^{-16}.$$

Point Shapley shares: composition 58.0%, denominator 26.2%, wage conditioning 1.2%; baseline structures growth 14.6%. The composition interval is 49.8–67.6%, so point dominance is not bootstrap-stable.

3. Wage pressure can cross the productive-capacity boundary

Boundary kept fixed in every run

$$y_t = \log Y_t^{NFC}, \quad k_t^{ME} = \log K_t^{ME}, \quad k_t^{NRC} = \log K_t^{NRC}, \quad \tau_t = k_t^{ME} - k_t^{NRC}.$$

State	Accounting boundary	Basis	Role
NFC_GVA	whole nonfinancial corporate sector	GVA	main state
NFC_NVA	whole nonfinancial corporate sector	NVA	authorized robustness
CORP_GVA	all corporations	GVA	comparison only
CORP_NVA	all corporations	NVA	comparison only

Economic sequence

wage-pressure boundary → choice of technique →
NFC capacity building

Identification limit

Fordist NFC/corporate correlations are 0.998 on both bases. Agreement establishes institutional robustness; it cannot identify a unique bargaining boundary. The GVA alias is exact and is not re-estimated.

4. Memory enters technique choice, not the output boundary

M0–M1: current state and finite memory

$$y_t = \alpha + \theta \tilde{k}_t^{NRC} + \psi \tilde{\tau}_t + \phi \tilde{d}_t + \lambda(\tilde{\tau}_t \tilde{d}_t) + \varepsilon_t,$$

$$m_{d,t}^{(h)} = h^{-1} \sum_{j=1}^h d_{t-j}, \quad h \in \{3, 5\}.$$

M2: embodied accumulation

$$Q_{\tau,d,t}^{(h)} = \sum_{s \leq t} (m_{d,s}^{(h)} - \bar{m}_{d,w}^{(h)}) \Delta \tau_s.$$

Wage pressure conditions newly installed technique; it does not revalue the existing stock.

M3: estimated adaptive memory

$$s_{d,t}(\rho) = \rho s_{d,t-1} + (1 - \rho) d_{t-1}, \quad 0 \leq \rho < 1,$$

$$Q_{\tau,d,t}^{(\rho)} = \sum_{s \leq t} (s_{d,s}(\rho) - \bar{s}_{d,w}(\rho)) \Delta \tau_s.$$

ρ is profiled on 0.00, 0.01, ..., 0.98 by
Restricted-DOLS BIC.

Estimator discipline

Main correction: manual intercept-only RDOLS LL11. Dynamic terms are restricted to differences of k^{NRC} , τ , and the relevant wage state. LL00/LL22 are sensitivities; FM-OLS/IM-OLS are frozen v6 audits only.

5. The estimated state is persistent; the main boundary is grid-censored

Adaptive-memory persistence profile, pre-1974

State	$\hat{\rho}$	95% block CI ^p	half-life
NFC-GVA	0.98	0.92–0.98	≥ 34.3 y
NFC-NVA	0.96	0.77–0.98	17.0 y
CORP-GVA	0.95	0.86–0.98	13.5 y
CORP-NVA	0.94	0.74–0.98	11.2 y

Structural elasticities are not the observed-direction ratio

M2-H3 and M3 pass the generated-path, rank, sample, and residual gates for both NFC definitions; the M2 interaction remains negative under H5. Yet NFC-GVA selects the upper grid boundary, so its half-life is a lower bound and persistence is classified as weak-or-boundary under the prespecified rule.

6. Verdict and implication for the v6 presentation

What the evidence establishes

- The red line is a realized-direction ratio, not an equilibrium parameter.
- Wage conditioning contributes only 1.2% of its first-difference roughness.
- Unbalanced ME/NRC growth is the point-dominant source (58.0%); denominator variation contributes another 26.2%.
- The 1945–46 observations account for 54.7% of attributed roughness, making the ratio data-sensitive under the prespecified rule.

Adjudication

The smoother-equilibrium expectation is not fully supported. Structural θ^{scale} and θ_t^τ are materially smoother and both NFC definitions agree, but the main adaptive state is grid-censored and influential capital-growth observations fail the full acceptance rule.

Revise v6 in three places

- ① Rename the red line “observed-direction capacity payoff (ratio diagnostic).”
- ② Report θ^{scale} , θ_t^τ , and g_t^p before dividing by g_t^{cap} .
- ③ Present embodied/adaptive memory as S90 robustness evidence, not as a replacement for the locked chapter specification.
